TITLE:

The Determination of  $\alpha$ -Phase Content in the Austenite  
Welded Butts by Means of the Magnetic Method (Opredeleniye  
soderzhaniya  $\alpha$ -fazy v austenitnykh svarnykh shvakh  
magnitnym metodom)

PERIODICAL:

Avtomaticheskaya svarka, 1959, Nr 1, p 43-48(USSR)

ABSTRACT:

The author describes the magnetic method for determining  $\alpha$ -phases. He proposes an empirical formula designed for the calculation of the intensity of magnetization saturation of multi-alloyed ferrite, taking into consideration the influence of basic alloying elements. The formula allows the use of the Armco-iron standards for determining the quantity of  $\alpha$ -phases in the austenite welded butt metal by means of the magnetic method. The author gives experimental data proving the correctness of the proposed formula.

TITLE: On the Brittle Nature of Chrome-Nickel Stainless  
Steel at 475°C

PERIODICAL: Avtomaticheskaya svarka, 1959, Vol 12, Nr 5 (74)  
pp 66-82 (USSR)

ABSTRACT: The article presents a discussion on the development of brittleness at 475°C in the weld metal containing 27.8% Cr and 9.7% Ni (65%  $\alpha$ -phase). Described are the theories of Heger (Ref. 4) and Cina and of Lavender (Ref. 8). The works of Lena and Hawkens (Ref. 2,3), Becket (Ref. 11), Zapffe and others (Ref. 7), Gosso (Ref. 6) and Newell (Ref. 13) are discussed. Some parts of the works of Kintzel and Franks are also presented. An experimental investigation of the alternating of microstructure, the impact strength, the microhardness of the ferrite and austenite phase and of the magnetic saturation were made. Investigated were also the deve-

On the Brittle Nature of Chrome-Nickel Stainless Steel at 475°C

lopment of Homogenization, the micro structure, micro-hardness and impact strength after heat treatment. For the investigation a weld metal was used, which was gotten by multiplied welding of steel 1 Kh/9N9T with wire type Co-OKh18N9. The welding was done under ceramic flux and the following conditions:  $I = 600 - 650$  A,  $U = 28 - 30$  V,  $V = 25$  m/h. The alternating of the microstructure of the metal was made by electrolytic etching in 10% oxalic acid (Fig. 2,3). To the authors there seems to be a possibility to set up following hypothesis, with the results of the experiment on the 475°C-embrittlement: The brittle condition is caused by a process of interphase redistribution of the chrome in high alloyed chrome-iron, without separation of the surplus phases. There exists a narrow connection between the 475°C- brittleness and the development of  $\sigma$ -phase, which takes place at a higher temperature. The interphase redistribution of chrome, which causes the 475°C-embrittlement, can be regarded as an "incuba-

tion" of the development of -phase. To eliminate the 475°C-brittleness, only the same way as eliminating the -phase is possible: To heat to temperature higher than 1000°C with added speedy cooling (Fig.5). There are 5 graphs, 5 figures, 2 tables and 15 references, 5 of which are Soviet, 7 English, 2 German and 1 French

TITLE: Effect of the alpha-phase content in austenite-ferritic weld metal on the development of 475°-brittleness

PERIODICAL: Avtomaticheskaya svarka, no. 4, 1961, 13 - 17

TEXT: Results are given of experiments with the  $\alpha$ -phase content in two-phase metal varied between 0 and 65%. One series of specimens was prepared using Cs-0X18H9 (Sv-OKh18N9) wire 5 mm in diameter and additional alloying with Cr through the flux, and a second series with Sv-OKh18N9 and three other wire grades with different nickel contents. Direct current with inverse polarity was used for all specimens. The series of alloying ceramic fluxes was composed using the slag-forming base of the K-8 flux for the base [Ref. 2: G. Bandel and W. Tofaube, Die Versprödung von hochlegierten Chromstählen im Temperaturgebiet um 500°, Archiv für das Eisenhüttenwesen, v. 15, no. 7, 1942]. The ferrite content in the deposited metal was determined with a D. C. Shteynberg magnetometer using the method described in same publication (Ref. 2). The embrittlement was determined by the relative reduction of the notch toughness in the brittle state. Notched specimens

TITLE: Effect of alloying elements on the 475C embrittlement of austenitic-ferritic weld metal 18

SOURCE: Avtomaticheskaya svarka, no. 7, 1963, 15-20 16

TOPIC TAGS: stainless-steel-weld 475C embrittlement, austenitic-ferritic-weld-metal embrittlement, ferrite-embrittlement effect, 475C embrittlement, stainless-steel weld, stainless-steel-weld alloying

ABSTRACT: The effect of alloying elements on the 475C embrittlement of austenitic-ferritic weld metal has been studied. Experimental submerged-arc welds (deposits and V-joints) were made on Kh18N9T [AISI 321] stainless steel plates with electrode wires of OKh18N9 [AISI 302], EI-606 [0.07% C, 20% Cr, 10% Ni, 2.2-2.7% V, 1-2% Mn, 1.3-1.8% Si], Kh22N15 [AISI 309], Kh25N20 [AISI 310], or Kh20Ni10Cr6 [0.12% C, 5-7% Mn, 1% Si, 18-22% Cr, 9-11% Ni]. The weld metal contained 17.88-23.6% Cr and 8.20-12.32% Ni and (added through flux separately or in combination) 0.86-1.63% Mo, 0.52-1.66% Si, 1.04-2.36% W, 1.41-3.20% Mn, and 1.00-1.56% V.

Card 1/2

L 14953-63

ACCESSION NR: AP3001115

2

The flat deposits contained 1.3-66.0% ferrite; the V-welds, 1.5-11.7% ferrite. The Mesnager notched bars cut from the weld metal were held at 475C for up to 2000 hr. Results of impact tests showed that susceptibility to embrittlement at 475C can be reduced by lowering the content of the  $\alpha$ -phase. Alloying of the weld metal with Mo, V, W, Si, or Mn does not eliminate the 475C embrittlement of the weld metal. On the contrary, all alloying additions accelerated the embrittlement process and lowered the notch toughness. However, at  $\alpha$ -phase contents below 10% the detrimental effect of alloying elements was less pronounced. Chromium appears to be the most harmful element, and the 475C embrittlement can be reduced by lowering the chromium content. The amount of  $\alpha$ -phase needed to prevent intergranular corrosion and hot cracking of welds can be maintained by alloying the weld metal with other ferrite formers. Orig. art. has: 2 tables and 4 figures.

The increase in winter hardiness and yields of red clover  
owing to fertilizers. V. V. Koperchinskii and K. A.  
Dmitriev. *Problems Animal Husbandry* (U.S.S.R.) 7.  
No. 4, 78-80 (in English, 90) (1969); cf. C. A. 34, 4847.  
Liming and phosphate treatment of acid podzol soils in-  
creased the yields and the winter hardiness of red clover.  
On acid soils without lime phosphates increased winter  
hardiness, while P + K decreased it. On limed soils the  
application of K decreased the winter hardiness, but to a  
smaller degree than on unlimed soils. K fertilizers were  
most injurious when applied as sylvite, probably owing  
to the poisoning by Cl. Least injurious was K<sub>2</sub>SO<sub>4</sub>.  
K can be applied for increasing the yields of clover in the  
form of K phosphate. At references. W. R. Hunt

**The influence of fertilizers on the wintering of clover**  
 V. V. Kuperzhinskiy, *Chemical Sciences*, 1964, 5, 8  
 203-204, 2031. Time, P and K added, no  
 proved the wintering over of clover on acid soils. This is  
 ascribed to the formation of more stable protein compounds  
 of the plasma. In the roots of clover there is an accumula-

tion of nonprotein N during the winter, especially the  
 amino acids and peptones as products of hydrolysis.  
 There was no correlation between the change in concn. of  
 sugars or of the osmotic pressure of the cell sap and  
 wintering over of clover. The chlorides of K decreased  
 the resistance to wintering. Phosphates increased the  
 respiration of clover, and because of that the wintering  
 over of the clover was reduced. I. S. Ioffe

Uptake and distribution of labeled phosphorus in extraradicle nutrition of opium poppy. V. V. Koperzhinskiy and V. V. Sheberstov. Doklady Akad. Nauk S.S.S.P. 106, 1001-4(1956).—Poppy plants were grown in NPK medium with 0.01 g. B added/vessel. In late summer the plants were sprayed with  $P^{32}$ -labeled phosphate and the plant parts were subsequently examined for  $P^{32}$  distribution. On the 3rd day the labeled P had moved to the lower leaves, roots, and generative organs; after 22 days the residue in the upper leaves declined as did that in lower leaves, but the content in the generative organs rose by some 30-fold. Thus, extraradicle supply of P is directed principally to these organs. If the spraying is directed at the lower leaves, the content of  $P^{32}$  in upper younger leaves shows a gradual increase with time. If  $P^{32}$  is introduced through the soil, its utilization is 400-1400 times more intensive than with spraying application. The results indicate that the poor assimilation of P through the leaves is responsible for lack of crop response to spraying methods in nutrition of poppy. G. M. Kosolapoff.

SUBJECT USSR / PHYSICS CARD 1 / 2 PA - 1837  
 AUTHOR KOPEC, Z.  
 TITLE On the Problem of the Effective Mass of Electrons and Holes in Germanium.  
 PERIODICAL Zhurn.techn.fis, 26, fasc.11, 2451-2458 (1956)  
 Issued: 12 / 1956

It is of interest to compare the data on the structure of its zone at its edge, obtained by the investigation of cyclotron resonance, with those obtained by the analysis of considerably more complicated effects (if the method of cyclotron resonance is not applicable). A possibility of solving this problem is offered by the analysis of the temperature course of the thermoelectromotoric force and the concentration of current carriers within the domain of admixture conductivity. At first the thermoelectromotoric force  $\alpha$  for a type of carriers is given; the formula derived for this purpose holds good on the following conditions:

- 1.) The expression for scattering is isotropic and permits the employment of a LORENTZ solution.
- 2.) Applicability of the usual method of effective masses.
- 3.) Phonons to be taken into account in connection with the temperature gradient according to DEBYE without correction for the lack of thermodynamic equilibrium.

For the analysis of the effective mass by means of the aforementioned formula for  $\alpha$  it is necessary to measure the three experimental quantities  $\alpha$ ,  $R$  and  $\sigma$  for a set of samples with different concentration of current carriers within a temperature range in which this formula describes the behavior of the thermoelectro-

Zhurn.techn.fis, 26, fasc.11, 2451-2458 (1956) CARD 2 / 2 PA - 1837  
 APPROVED FOR RELEASE: 03/13/2001 CIA-RDP86-00513R000824510013-

motoric force sufficiently well. This analysis is above all suited for substances with predominantly atomic binding, e.g. germanium. The mechanism of scattering can be taken into account in the case of germanium-monocrystals and -polycrystals.

As a criterion for the applicability of the above formula for  $\alpha$  for the analysis of the thermoelectromotoric force the temperature course of  $\alpha$  may be taken: the effective masses determined by the analysis of germanium samples (8) are shown in a table. According to these data the effective mass computed for electrons is larger than the effective mass computed for the holes (within the concentration- and temperature-range under investigation). However, analysis of the data on current carriers in Ge is known to produce a contradictory result. This contradiction may be explained by considering the complicated structure of the zones in Ge. One of the conditions for the correctness of the aforementioned equation for  $\alpha$  loses its validity, and the formulae must be changed accordingly. Nevertheless, the numerical results obtained here probably retain a certain importance. According to a newly carried out computation of the effective mass included within the concentration formula, the results obtained by the author are in quite good agreement with the data corresponding to cyclotron resonance.

TITLE:

Formation of the  $\sigma$  Phases in the Rhenium-manganese and  
Rhenium-iron Systems (Obrazovaniye  $\sigma$  -faz v sistemakh  
reniy-marganets i reniy-zhelezo)

PERIODICAL:

Doklady Akademii nauk SSSR, 1959, Vol 125, Nr 1, pp 87-88  
(USSR)

ABSTRACT:

Among the numerous known binary and ternary systems of transition metals  $\sigma$  phases are observed, i.e. compounds with an isomorphous structure of the  $\beta$ -U type. According to modern opinions the condition for the formation of the  $\sigma$  phase is as follows: if one of the components belongs to group VII or VIII of the periodic system the second component must be of group V A or VI A. However, the  $\epsilon$  phase of the iron-rhenium system has also a crystal lattice of the  $\sigma$  phase (Refs 1, 2). Since the latter system does not correspond to the above-mentioned condition the  $\sigma$  phase cannot be explained within the framework of the existing theories (Refs 3, 4). The alloy produced by the authors showed a diffraction pattern confirming the data from reference 1 (Table 1). Lattice temperatures were:

TITLE:

On the Question Regarding the Plasticity<sup>76</sup> of High-temperature Modifications of Polymorphous Metals

PERIODICAL: Doklady Akademii nauk SSSR, 1960, Vol 131, Nr 5, pp 1137-1139 (USSR)

TEXT: It is stated by the authors that the rule established by Ye. M. Savitskiy with respect to the plasticity of high-temperature modifications of polymorphous metals is of great importance for physics. It obviously points to the close relationship between polymorphism and electron-structural change in the atoms of polymorphic metals with temperature. According to the mentioned rule, the highest-temperature modification of a polymorphous metal must show the highest plasticity. It must have a crystalline structure of the cubic type promoting plastic deformation, i. e. predominantly a face-centered one. From the mentioned rule, some theoretically and practically important conclusions were drawn. It has been also repeatedly confirmed (Refs 2,3). In table 1, polymorphous metals together with their crystalline structures and the temperatures of transition from one modification to another are shown. Table 1 illustrates the Savitskiy rule (tin being an exception). The rule can be obviously explained by the fact that the simpler symmetrical crystalline structures are more stable in all high-

temperature phase transitions. That is because they have a lower free energy and a higher entropy. It can be presumed that the polymorphous modifications of the matter are formed as the result of electron-structural changes in the bound atoms and in consequence of the corresponding qualitative changes in the inter-atomic bonds with temperature (Ref 4). The portion of metallic bonds is apparently increased by higher temperatures. There is evidently a relationship between the electron state of the bound metal atoms, the number of electrons per atom, or the electron concentration and temperature changes. The individual polymorphous modifications correspond to different electron states and to a different electron concentration. The authors make reference to the zone theory of metals involving packing of zones, by Brillouin, and to the theories by H. Jones (Ref 5) and Yum-Rozeri (Refs 6 - 9). From table 1, it is evident that with polymorphous metals except calcium, strontium, and tin polymorphous transitions at temperature decreases take place in a way to maintain a certain sequence of crystal-structural changes: K12(K8) → G12 (the more complicated one). At a temperature decrease, a closely packed hexagonal structure instead of a face-centered or a body-centered cubic structure forms (with several exceptions). From this, the authors conclude that in the crystalline structure of the polymorphous modifications (except calcium and strontium) a successive increase in the limit

Card 2/3

electron concentration takes place. Crystalline structures with higher limit electron concentrations are more stable at lower temperatures, while the high-temperature modifications have a lower limit electron concentration. The authors assume that a polymorphous substance passes a successive series of states when temperature is decreased each of which is characterized by a defined electron concentration. This concentration steadily increases with the temperature decrease; it also produces a successive change in crystal structures. The authors also come to the conclusion that the number of free electrons in an atom of polymorphous metals increases with decreasing temperature. With iron, manganese, plutonium, and thorium, the mentioned sequence is not observed. There are 1 table and 9 references, 7 of which are Soviet.

TITLE: Properties of single crystals prepared by electron-  
beam zone melting

PERIODICAL: Akademiya nauk SSSR. Izvestiya. Otdeleniye  
tekhnicheskikh nauk. Metallurgiya i toplivo,  
no. 6, 1961, 74 - 78

TEXT: The properties of high-purity W, Re, Ta, Mo, Nb and V  
were studied on single-crystal specimens prepared by electron-  
beam zone melting (5 - 8 passes at 8 - 10 cm/h) from sintered-  
powder compacts (2 - 5 mm in diameter) preliminarily degassed by  
vacuum treatment at 1 800 - 2 500 °C. It was confirmed by X-ray  
diffraction study that single crystals were, in fact, obtained  
by this method. No preferred crystal-growth orientation was  
observed and, in some cases, there was evidence of a slight  
( $< 0.5^\circ$ ) block misalignment. The existence of sub-boundaries  
was revealed by metallographic examination. The results of  
hardness measurements are reproduced in Table 1, where columns

Properties of single crystals ....

I and II relate, respectively, to single crystals prepared by electron-beam zone melting and vacuum arc-melted buttons. UTS of Ta single crystals was 20.8 kg/mm<sup>2</sup>, the corresponding figures for Mo and Nb being 41.7 and 17.2 kg/mm<sup>2</sup>. In every case, the reduction in area amounted to ~100%. High plasticity of the zone-melted specimens was indicated also by the fact that single Mo crystals could be bent over a radius of 4-5 mm and could be reduced by cold-working to foil 0.2 - 0.3 mm thick or to wire 1 - 1.5 mm in diameter; Single V crystals could also be reduced to foil 0.15 mm thick. The purity of the single crystals of the metals studied was determined by determining the  $\rho_{3000K} / \rho_{4.20K}$  ratio, where  $\rho$  denotes the electrical resistivity at the respective temperatures. This ratio was 1 400 and 900, respectively, for single W and Mo crystals, the corresponding figure for these metals melted in a conventional manner being 10 - 20. The results of the present investigation indicated that high-purity single crystals could be prepared by electron-beam zone melting.

TITLE: The phase diagram of the manganese - rhenium system

PERIODICAL: Zhurnal neorganicheskoy khimii, v. 6, no. 6, 1961, 1474-1476

TEXT: Since only provisional data are available on the manganese - rhenium system, the latter was checked by micro- and X-ray structural analysis, thermal analysis and investigation of the microhardness of the phases. Part of the results is given in the phase diagram (Fig. 1). Since the fusing point of rhenium at 3160°C lies much higher than the boiling point of manganese at 2090°C, Mn-Re alloys could only be melted up to 30 atom % Re in the vacuum induction furnace in Ar atmosphere. Electrolytic manganese (99.83%) and pressed rhenium powder (99.8%) sintered at 1500°C served as initial substances. Alloys with 0.2; 0.3; 0.5; 1.87; 2.64; 3.1; 5.56; 9.65; 10.72; 17.05; 20.42; 22.9 and 32.1 atom % rhenium content were investigated. Hardening was done at 950°C for 100 hr. It was established by microstructural analyses that  $\alpha$ -Mn dissolves up to

Card 1/4

B110/B206

The phase diagram of the ...

5.5 atom % Re. From this content on, the structure of the alloy is a diphasic one. The  $\sigma$ -phase (52.24 atom % Re) forming during the peritectic reaction is separated dendritically and increases with increasing rhenium content. The radiographs, the results of which coincide with those of the microstructural analysis, were taken in the PKY (RKU) and PKD (RKD) chambers with  $\text{CrK}_{\alpha}$  - and  $\text{V K}_{\alpha}$  emissions. The structure of the solid

solution is that of  $\alpha$ -manganese. The parameter of its crystal lattice changed from 8.894 kX (pure Mn) to 8.924 kX at a 5.56 atom % Re content and then remains constant. From about 9.5 atom % Re, interferences of the  $\sigma$ -phase which increase with increasing Re concentration can be observed. The parameters of the crystal lattice of the  $\alpha$ -phase with 22.9 atom % Re are:  $a = 9.11$  kX;  $c = 4.92$  kX;  $c/a = 0.54$ . No  $\beta$ -Mn interferences were established. The thermal analysis was made with the W-Re thermocouple  $\beta$ P 5/20 (VR 5/20) according to the method described by the first author: Dokl. AN SSSR, 129, 559 (1959). It was established that rhenium admixtures  $> 5.54$  atom % lead to the increase of all temperatures of the polymorphous transitions and the fusing temperature of Mn-Re. The temperature of formation of the  $\sigma$ -phase (presumably  $< 1700^{\circ}\text{C}$ ) could not be determined. The analogous metals of the VIIth

Card 2/4

The phase diagram of the ...

group of the periodic system rhenium and manganese form, against the rule, no continuous series of solid solutions. The  $\sigma$ -phase forms at 52.24 atom % Re content, the range of solid solutions only goes up to 5.5 atom % Re content. This probably produces the relationship of the  $\alpha$ - and  $\beta$ -modifications of Mn forming at low temperatures, with the inter-metallic compounds ( $\gamma$ - and  $\delta$  phases) on the basis of its interatomic bond type, the crystalline and physical properties. In contrast to Ti, Zr, Nb and Ta, rhenium is soluble in  $\alpha$ -Mn up to 5.5 atom %, and the structure of the  $\beta$ -modification is not undercooled. This confirms the favorable value of the size factor of Re as a cause for its solubility. There are 2 figures and 4 Soviet-bloc references.

TITLE: Solubility of chemical elements in manganese

PERIODICAL: Akademiya nauk SSSR. Izvestiya. Otdeleniye  
tekhnicheskikh nauk. Metallurgiya i toplivo, no.4,  
1962, 157-161

TEXT: An attempt was made to use the established general principles of the formation of metallic substitutional solid solutions to estimate the solubility of various elements in allotropic modifications of manganese. It was shown that solid solubility is satisfactorily defined by three factors: size (atomic radii), chemical and crystallographic. Of 21 elements for which the dimensional factor is favourable and which are electro-negative with respect to gamma-manganese, 17 form regions of limited solid solutions with over 5 atomic %, and only 4 have a low solubility (under 1-2 atomic %). The chemical factor is most conveniently expressed through the difference in electro-negativity. For gamma manganese a continuous range of

Card 1/2

Solubility of chemical elements ... S/180/62/000/004/008/009  
E111/E183

substitutional solid solutions is formed if the size factor

$$P = \frac{R_A - R_B}{R_B} \cdot 100\%$$

is between 0 and -5% (where  $R_A$  and  $R_B$  are the atomic radii of the solute and manganese, respectively), if the difference between the electronegativity of manganese and the solute is between 0.1 and 0, and if the crystal lattices correspond. Rather similar relationships hold for beta-manganese, but not for the alpha modification, probably because of its complicated structure. It is concluded that the method studied is suitable for estimating the solubility of various elements in metals. There are 2 figures.

chemical compound was detected. All these metals increase the Pd melting point; W is particularly effective in this respect: with 20% W, the alloy melting point is 2,000C and the peritectic-reaction point is 2,175C. The micro-hardness, and effect of thermal treatment of the above alloys were investigated. Resistivity was measured at 25 and 100C; all additions increase the resistivity of Pd; a Pd+20% W alloy has 107-110 microhms-cm and a temperature coefficient of  $(4.5-7) \times 10^{-5}$ ; coupled with Cu, this corrosion-resistant alloy develops 3.9 microvolt/degree; its ultimate strength, 65 kr/mm<sup>2</sup>, with elongation up to 30%. TITLE: Characteristics of the plastic deformation and mechanical  
 properties of some intermetallic compounds 27

SOURCE: AN SSSR. Izvestiya. Metallurgiya i gornoye delo, no. 6, 1964,  
 129-136

TECH TAGS: intermetallic compound, plastic deformation, mechanical  
 effect, temperature effect, Fe<sub>2</sub>Ta compound, Fe<sub>2</sub>Zr compound, NiAl  
 compound, Ni<sub>3</sub>Ta compound, Ni<sub>3</sub>Nb compound, Ni<sub>3</sub>Al  
 compound 27 27

ABSTRACT: The effect of crystal structure on the deformation behavior of  
 NiAl-type intermetallic compounds has been studied. Deformation  
 was carried out by compression at temperatures ranging from -196C  
 to melting temperature. In Ni<sub>3</sub>Nb single crystals at room tem-  
 perature, slip occurred along the (010) plane. This is probably true  
 of Ni<sub>3</sub>Ta compound which is isomorphic with Ni<sub>3</sub>Nb. (The Ni<sub>3</sub>Nb compound  
 has a CuTi-type c.p.h. lattice with the constants 5.10 and 4.52 kX)

Card 1/3

L 22209-65

ACCESSION NR: AP5001615

Additional slip planes were observed in polycrystalline  $Ni_3Nb$ . Great differences in the temperature-induced softening of ductile  $Ni_3Al$ ,  $Ni_3Nb$ ,  $Ni_3Ta$ ,  $Ni_3Ti$ , and brittle  $Fe_3Cr$  and  $Fe_3Ta$  compounds were observed (see Fig. 1 of the Enclosure). The  $NiAl$  compound, which at room temperature has a compressive strength of about 62 kg/mm<sup>2</sup> and is brittle, softened at 800C to such an extent that it sustained 10% compression without failure. It is concluded that crystal structure is the main factor determining the compression strength and behavior of metallic compounds at high temperatures. Orig. art. has: 5 figures and 1 table. [MS]

TITLE: Production and properties of single crystals of refractory metals and alloys

SOURCE: AN SSSR. Institut metallurgii. Svoystva i primeneniye zharoprochnykh spлавov (Properties and application of heat resistant alloys). Moscow, Izd-vo Nauka, 1966, 15-24

TOPIC TAGS: refractory metal, refractory alloy, single crystal, molybdenum, niobium, tungsten

ABSTRACT: The two main methods for production of metallic single crystals are extraction from a melt by the recrystallization method, and zone refining. The method of extraction from a melt by seeding is widely employed industrially for growing large single crystals of germanium, silicon (up to 80 mm in diameter), and semiconductor compounds of varying composition for diodes, transistors, and condensers. Application of this method to refractory metals has not been widely developed. The article describes in detail the techniques of zone refining. In vertical zone melting without a crucible, the ratio of the surface tension to the density of the melt should be

Card 1/2

ACC NR: AT6034432

100:1 or greater. The maximum size of single crystal rods produced by this method is, for example, 14-16 mm for molybdenum and 6-8 mm for tungsten, with a length of the order of 200-250 up to 500 mm. A table shows the purity and mechanical properties of rhenium of different degrees of purity, including the mechanical properties under elongation stress, the hardness, and the temperature of the start of recrystallization. A further table lists the mechanical properties of single crystals of various alloys of the refractory metals. It is found that an increase in the purity of zone refined molybdenum considerably lowers its resistance to deformation. Based on experimental results, a series of figures illustrate the substructure of single crystalline alloys, the mechanical properties of single crystal alloys of the molybdenum-niobium system, and the microhardness of alloys of the molybdenum-niobium system. P. M. Nosov, N. P. Khazov, A. Ye. Tsutskov, and T. S. Stronina took part in the work. Orig. art. has: 6 figures and 3 tables.

TITLE: Nature of the secular cycle

SOURCE: Priroda, no. 9, 1966, 80-83

TOPIC TAGS: solar activity, sunspot, solar cycle, solar phenomenon, solar radiation intensity

SUB CODE: 03

ABSTRACT:

The article cited below gives a concise insight into some aspects of the clearly expressed 11-year period in the number of observed sunspot groups and the secular variation of the height of the maxima on individual 11-year periods. The author notes that for study of the patterns of periodicity of sunspots the number of observed groups is not primary and therefore is not the best index. The number  $N$  of sunspot groups which exists on the sun at a particular time is dependent on how many groups ( $f_0$ ) appear on the sun in a unit time and their mean

Card 1/2

0933 2162

ACC NR: AP7013703

life time ( $\bar{T}$ ). The parameters  $f_0$  and  $T_0$  can change with time independently of one another. If it is desired to determine the periodicity of the spots it is necessary to study directly the temporal changes of these two indices and not the number  $N$  of existing spot groups. Study of the primary indices  $f_0$  and  $T_0$  makes it possible to investigate the periodicity of sunspots from two physically different points of view simultaneously;  $f_0$  — the index of frequency of the phenomenon, reflects the quantitative aspect of the spot-forming process, whereas the mean lifetime  $T_0$  of spot groups is an index of the intensity of the phenomenon and reflects the qualitative aspect of the process. The 11-year period is manifested only for the number  $f_0$  of forming spots, whereas it is virtually not traced for the mean duration  $T_0$  of spot groups. The secular cycle is characteristic only of the mean lifetime of spot groups and is virtually not manifested in the number of forming spot groups. The 11-year and secular cycles of solar spot-forming activity therefore have a different physical nature: the 11-year cycle is associated with the number of forming spot groups and the secular cycle is associated with their mean intensity. The secular cycle is manifested not only in the mean lifetime of the spot groups, but also their mean intensity. At the time of the maximum of the secular cycle there is an increase of the number of groups with a large lifetime, but groups with the same lifetime attain a still greater area than at the time of the minimum of the secular period. Kopey, A.A.

✓ Increased wear resistance and quality of cotton fabrics. A.A. Kopey (Tekstil. Prom., 1954, 14, No. 10, 31-33). —Ammoniochloride, a new reagent for bleaching cellulose and cellulose hydrates, was found more stable than  $\text{NaClO}$  solutions; it damages the cellulose much less, even when using solutions with 4-8 g./l. of active chlorine. A new finishing agent for cellulosic fabrics is also reported, which is prepared by introducing bleached cotton lye or regenerated cellulose waste gradually into Na zincate containing 90-100 g./l. of  $\text{NaOH}$  and 20-25 g./l. of  $\text{ZnO}$ , the mixture being mechanically stirred and cooled at  $-5^\circ$  to  $+5^\circ$  for 14-2 hr. The solution obtained is transparent and homogeneous and does not contain undissolved fibres. For finishing, solutions containing 1-5-3% of cellulose are applied to the fabric at temp.  $+40$ - $50^\circ$ ; the impregnated fabric is then immersed in an acid bath to coagulate the finishing agent, and rinsed. Condensation of the finish can be obtained by treating the fabric with hot water ( $60$ - $80^\circ$ ) and also with conc. alkali solution. In this way, the application of the finish can be combined with mercerisation to obtain a better effect and to increase the wear resistance of the fabric by 25-30%. J. Text. Inst. (R.D.C.).

Title: The Effect of Composition on the Firing Properties of Semi-Porcelains

Original  
Periodical: Steklo i keramika, 1956, No 5, 13-15

Abstract: Semiporcelains containing large amounts of argillaceous materials (50-60%) are characterized by low expansion coefficients (EC) of the body ( $5.26-4.46 \times 10^{-6}$ ). Semiporcelains containing 40-45% argillaceous materials have a higher body EC ( $5.83-6.31 \times 10^{-6}$ ). At constant argillaceous content the substitution of feldspar for silica sand lowers the EC of the body. A reduction in the amount of argillaceous material by raising the quartz content by 2, 7, and 17% leads to an increase in the EC from  $5.06 \times 10^{-6}$  to  $6.25 \times 10^{-6}$ . It is more

TITLE:

Urgent Problems of the Further Development of Ceramics' Industry (Neotlozhnyye voprosy dal'neyshego razvitiya promyshlennosti stroitel'noy keramiki). From a Speech at the Meeting of Building Specialists (Iz vystupleniya na soveshchaniy stroiteley)

PERIODICAL:

Steklo i Keramika, 1958, Nr 5, pp 12-14, (USSR)

ABSTRACT:

The first and most important problem must be seen in the selection of the type and the construction of furnaces for firing, as these are the basis for ceramics production. The batch types operating at present must be replaced by tunnel kilns. The firing cycle in the Kirov factory is 32 hours; in periodic types it is, however, 93 hours. In batch types of the Slavuta factory 2420 kg of ideal fuel was consumed, and in the tunnel kilns of the Kirov factory this figure was 1220 kg per ton of products. In the years 1953-1954 the factories Katuarovskiy, Kuchinskiy, Smolenskiy, Voronezhskiy, Khar'kovskiy, L'vovskiy and Tbilisskiy were put into operation. The projects provided a special technology as well as an output of 20% colored tiles. In reality all this never left

Card 1/4

Urgent Problems of the Further Development of Ceramics' 72-58-5-4/18  
Industry. From a Speech at the Meeting of Building Specialists

the stage of blue print. Instead of muffle-tunnel kilns those tunnel kilns with open ~~flame~~ were put up. As a result of this the firing is carried only in saggers and only white tiles of low quality are produced. The share of manual labor is 70%, the waste figures are high etc. This problem has been discussed in the course of many years and the decisions made were in favor of muffle- and electric tunnel kilns: such decisions were made by: the Tekhsovet MPSM USSR (July 1956), the All-Union Conference of Ceramics at Shchekino (April 1957), the Conference of Ceramists in ~~Ukraine~~ <sup>Ukrainia</sup> and the MPSM of the Ukrainian SSR (1956-1957) and finally by the MPSM College of the USSR (May 1957). Further discussion might be futile here. At present the practical execution of these decisions must be arranged. This is one of the urgent problems. No less important is the problem of the creation of a new type of high-capacity ceramics factory operating with concentrated raw material as well as with supplied finished powder mixtures in collaboration with other branches of industry. The preparation of the raw materials should take place at their places of production; the production of dyes should

Card 2/4

Urgent Problems of the Further Development of Ceramics' 72-58-5-4/18  
Industry. From a Speech at the Meeting of Building Specialists

take place in special factories in order to relieve the ceramics factories and to obtain the raw materials and dyes of better quality and at cheaper prices; this is also practiced abroad. The author mentions as an example, the American ceramics industry which produces 5-times as much as the Russian with only twice as much labor as the USSR; this is said to be the result of specialized production and extensive collaboration. According to a calculation the transport costs of the raw material in the case of its concentration at the places of production could be reduced by 25-30%, the costs of raw material preparation by 30% and the general costs of ceramics factories for raw materials by 20%. The most important problem of the building-ceramics industry is the widening of the assortment of ceramic casings, as well as the use of local clay for their production. The composition of the glaze as well as the technological parameters were worked out by the NIISTROYKERAMIKA Institute. The experimental plant of the institute has acquired great experience in the mass production of colored and decorated tiles. It is only that the factories must build small-scale electric furnaces of

Card 3/4

Urgent Problems of the Further Development of Ceramics' Industry. From a Speech at the Meeting of Building Specialists 72-58-5-4/18

modern design. The experiment of the NIISTROYKERAMIKA in 1958 showed that from the clays used in the tile works of the Economic Councils of Kalinin, Gor'kiy and Moscow, high-quality and cheap colored tiles can be produced.

AUTHOR: Kopeykin, A. A. SOV/72-53-10-4/19

TITLE: Influence Exercised by Additions of Fluxing Agents Upon Structure and Properties of Semi-Porcelain (Vliyaniye flyusuyushchikh dobavok na strukturu i svoystva polufarfora)

PERIODICAL: Steklo i keramika, 1958, Nr 10, pp 18-22 (USSR)

ABSTRACT: Besides feldspar dolomite, nepheline-syenite, mariupolite, and spodumene were used as fluxing agents. Already in 1932, A. Ye. Fersman, Member, Academy of Sciences, USSR, and, during World War II, Professor I. I. Kitaygorodskiy pointed to nepheline syenite. V. M. Permyakov and Z. A. Nosova also underlined in their papers the part they play. The properties of faience, semi-porcelain and porcelain masses depend to a considerable extent on the structure of the products as can be seen from the papers of P. A. Zemyatchenskiy (1924), I. F. Ponomarev (1929), A. M. Sokolov (1932), N. M. Chervinskiy (1941), V. V. Lapin (1948), P. P. Budnikov (1951), D. S. Belyankin and others. Petrographic investigations were carried out by the senior scientific cooperator of NIISTroykeramika, M. Ye. Yakovleva, as well as X-ray investigations by the junior scientific worker T.S. Butt.

TITLE: Semiporcelain Obtained at Reduced Burning Temperature  
(Polufarfor, poluchayemyy pri ponizhennoy temperature obzhiga)

PERIODICAL: Steklo i keramika, 1958, Nr 11, pp 28 - 33 (USSR)

ABSTRACT: The plan for the years 1959-1965 provides for the development and introduction of new body- and glaze formulas for reduced burning temperatures. The investigations of the NII Stroykeramika showed that this is possible for semiporcelain productions, and even results in an improvement in quality. Table 1 shows the weight compositions and table 2 shows the chemical composition of the initial materials. In table 3 the physical properties of the experimental bodies are listed. Furthermore a series of different experimental bodies is described. In figure 1 the dependence of the coefficient of thermal expansion upon the feldspar content is illustrated. Figure 2 shows the influence of the addition of dolomite, whereby the burning temperature falls somewhat. The substitution of feldspar by spodumene and ayanite reduced the burning temperature even further (Figs 3, 4, 5

Exhibition of Products and Equipment of the Italian  
Ceramics Industry (Vystavka izdeliy i oborudovaniya  
keramicheskoy promyshlennosti Italii)

PERIODICAL:

Steklo i keramika, 1958, <sup>15</sup>№ 12, pp 34- 37 (USSR)

ABSTRACT:

A group of Soviet experts visited this exhibition in  
Vincenza in 1957. Their attention was specially  
attracted by small tiles to be employed for the  
lining of tall buildings (Fig 1), 2 hydraulic presses  
(Figs 2 and 3), an electric 2-tunnel kiln for burning  
mosaic tiles (Fig 4), an electric 3-tunnel kiln for the  
burning of faience and procelain without molds (Fig 5),  
an annular tunnel kiln featuring a rotating bottom  
and a common feeding and unloading installation (Fig 6).  
The author stated that this exhibition gave evidence  
of a remarkable technical post-war modernization of  
Italian ceramics industry, with the latest achievements  
in this field being introduced. There are 6 figures.

TITLE:

The Ceramic Industry Requires Modern Muffle Furnaces and Electrical Tunnel Kilns (Keramicheskoy promyshlennosti nuzhny sovremennyye mufel'nyye i elektricheskiye tunnel'nyye pechi)

PERIODICAL:

Steklo i keramika, 1959, Nr 6, pp 1-7 (USSR)

ABSTRACT:

In the present paper the author deals with the types of drying and burning kilns employed in the ceramic industry of the USSR. Periodically operated kilns were used up to the fifth Five-year-plan. Towards the end of the fifth Five-year-plan. 90 % of tiles and 46 % of sanitary ceramics were burned in tunnel kilns, the burning cycle of which is almost three times shorter and the output three times higher, as was practically proved by the Kirov Works for sanitary faience in 1958. In 1958 experts of the Gosstroy USSR and of the Giprostroyaterialy visited foreign works of the ceramic industry and found a variety of types of kilns used that were adapted to the characteristics of the various productions. These experiences however were not taken into account for the Soviet practice and the new tile works at Katur, Kuchinsk, Smolensk, Tbilisi, Voronezh, Khar'kov, L'vov were further on

Card 1/3

The Ceramic Industry Requires Modern Muffle Furnaces and Electrical Tunnel Kilns SOV/72-59-1-1/13

equipped with the Giprostroymaterialy type flame furnaces in 1953 to 1955. These works were referred to by the "Stroitel'naya gazeta" newspaper as "new works using old-fashion technology". The coordinating conference of the functionaries of the ceramic tile industry held in December of last year at the Institut novykh stroitel'nykh materialov ASia SSSR (Institute of Modern Building Materials, ASia USSR) requested the Gosstroy USSR and the Gosplan USSR to facilitate further erection of Giprostroymaterialy type kilns for new tile works. The author of this paper laid special stress on the following three claims which according to his opinion should be respected when erecting further burning kilns for tiles: the burning temperature curve regulated in the kiln must be maintained; the kiln should be operated in a gas ambient free from combustion products, in which connection the studies of Z. A. Nosova and M. Ye. Yakovleva were mentioned (Footnote 1); a moldless burning of the products ought to be made possible. With the elimination of the calibrating devices in the production of the Soviet tile factories the necessity arose of assorting tiles according to their dimensions thus

Card 2/3

The Ceramic Industry Requires Modern Muffle Furnaces and Electrical Tunnel Kilns SOV/72-59-6-1/18

leading the Trust Mosotdelstroy Nr 2 to employ about 600 workers for this purpose and the apparent economy turned out to be a waste of State finances. The muffle furnaces and tunnel kilns allow a moldless burning of products, which includes considerable advantages and signifies a reduction of the cost price up to 25%. Figures 1 to 4 show the setting of tiles in caskets, molds and furnace lorries for burning. Figures 5 to 7 show the setting of sanitary-technical articles in muffle and electrical furnaces. Figure 8 shows a multi-channel muffle furnace and figure 9 a three-channel type electrical furnace. There are 9 figures and 3 references, 2 of which are Soviet.
